KEYMACRO is an advanced and often complex metering tool which allows you to control the metering system in a way that is different from the way normal Steinberg VST metering works. This makes it possible to hear exactly the effects you desire without compromising on the quality of your recordings. WHY USE THE PROGRAM Whenever you want to raise or lower the output level or change the balance (50/50) of one channel (mono) while maintaining the overall balance between the two stereo channels (balanced), you have to use a program such as ALBUM2PA. This is because Steinberg VST (software virtual synth) programs do not allow you to change the balance between the two stereo channels and are unsuitable for such tasks. KEYMACRO allows you to do this by using a digital signal processor (DSP) in addition to the standard Steinberg VST metering. This DSP or DSP engine is called the 'DSP2VST' or 'VST2DSP'. DSP2VST processes the incoming MIDI notes and converts them to voltages which are then sent via MIDI to the Steinberg VST. Sometimes you will want to apply some sort of processing to the notes that are output by your Steinberg VST program. An example is the conversion of the MIDI note level into a frequency which is used to divide the frequency response of the cabinet so that you can know how much of the frequency range is actually playing. By default the notes coming out of the Steinberg VST are normalised, which means that they are converted to a single number which represents their level. This conversion is what takes place in ALBUM2PA when you raise the output level in the sound editor. This function is also available in normal Steinberg VST plug-in software, but is limited to the measurement of the overall output level, the output level of a single instrument or the output level of one or more instruments after they have been blended. For more complex tasks such as normalising or raising the level of one channel of a mono plug-in there are no other choices available. In the KEYMACRO version of Steinberg VST plug-in software you can not only raise the output level of a single instrument, but you can also change the ratio of the outputs from the two stereo channels. One example is normalising the level of a particular instrument. By normalising the level you mean that the level of that instrument is raised 70238732e0

A lot of people use Skype as one of their primary communication methods. They like it because you can share your desktop screen with others and get things done more easily than you can with email. Although Skype isn't the most powerful and reliable program on the market, it has been improved over the years and its functionality is far better than ever.
